

A Guide to the CDS Package

Heidi Chen,^{*} David Kane,[†] Yang Lu,[‡] Kanishka Malik,[§] and Skylar Smith[¶]

June 23, 2014

1 Introduction

Over the past three decades, **credit derivatives** have become increasingly common tools for financial institutions that wish to pass on **credit risk** to investors who accept that risk for a premium, or fee. To put it simply, credit risk is the possibility that a borrower will default on his or her loan. In the modern financial world, there are many types of credit derivatives, including collateralized debt obligations (CDOs) and collateralized loan obligations (CLOs). In this vignette, we will focus on **credit default swaps** (CDSs), a type of credit derivative that has become quite popular among pensions funds, hedge funds, and investment banks, among other financial institutions (see Figure 1). We will explain the mechanics of this financial product and show how our **CDS** package can be used to manipulate and calculate relevant information associated with CDSs.

Credit Default Swap Market Size

Figure 1: CDS notional outstanding from 1997-2009.

[¶]sws2@williams.edu

CDSs originated in the late 1980s and were popularized by a team at J.P. Morgan that included Blythe Masters (Lenzner, 2009; Lanchester, 2009). The CDS market started to develop soon afterwards as banks used CDS contracts to hedge their credit exposures on balance sheets. Many different types of CDSs have since emerged including basket default swaps (BDSs), index CDSs, credit-linked notes, et cetera (Kallianiotis, 2013). In the **CDS** package, we focus on calculations related to single-name, or corporate, credit default swaps.

2 CDS Mechanics

2.1 Why CDSs?

To understand the benefits of CDSs as hedging tools, consider the following example:

Let's say that a pension fund portfolio manager has to allocate her clients' money (a total sum of \$100 million) such that it earns a steady return without being in a high-risk position. Therefore, this portfolio manager decides to buy several bonds from a company that has a low **credit risk**—say, Alcoa Inc. A **bond** is an agreement in which one party lends money to another party in exchange for that same sum of money, plus interest, at a future date. So, the portfolio manager lends money to Alcoa Inc., which she believes will not **default** on its debt, or render itself unable to pay back its bondholders. A company that has a low probability of default is said to have a low credit risk, and thus be **credit worthy**.

Since our portfolio manager is risk-averse, she chooses to buy senior debt. Her decision is in line with her interests since a company's bondholders, or debt holders, are compensated before a company's shareholders in the case of default. In other words, if a company defaults on its bonds, the company's remaining assets go first to the bondholders. Furthermore, both bonds and equity can be categorized as "senior" or "junior" (there exist many other classifications, but we'll stick to these two for now). As the terms suggest, senior bonds usually have the greatest seniority in the issuer's capital structure and are repaid in the case of default before junior bonds.

Such low-risk bonds are classified as **Investment Grade** (IG). The creditworthiness of a company is often represented by the **credit rating**—a score determined by rating agencies such as Standard & Poor's (S&P) or Moody's. We will not go into the details of how these ratings are determined; we only note that an Investment Grade bond has a rating of BBB- or higher from S&P or Baa3 or higher from Moody's. Let's say that our portfolio manager's bonds have a maturity of five years and a coupon rate of (TBD). Alcoa Inc. has a credit rating of (TBD) from S&P.

However, six months after the manager bought the bonds, her confidence in the creditworthiness of Alcoa Inc. begins to waiver. In other words, the manager is worried about some **credit event** related to the company. A credit event can signify the risk of a company's bankruptcy and resulting default, but the term can also expand to include failure to pay out debt within a certain amount of time, a substantial decrease in credit rating or the confiscation of assets, among other events. The company's credit rating or some other indicator of the company's credit risk may incentivize the manager to hedge

her position and reduce her portfolio's exposure.

Of course, she could simply sell the bonds; however, that may be premature or even unprofitable. Instead, she could purchase a financial product that has a value that rises with a drop in the bonds' intrinsic value. In other words, she could take a position that allows her to *profit* from increased credit risk.

One conventional technique of doing this is shorting bonds. Shorting is the process of borrowing and selling a security with the obligation to repurchase it in the future and return it to the lender. Clearly, this is profitable if the value of the security drops by the time it is repurchased in the future. However, there are several issues associated with this method. It is difficult to short securities that are not liquid. The portfolio manager may not be able to find enough bonds that will mature at the same time. Moreover, she would have to spend \$100 million to hedge her entire portfolio of \$100 million, which is a substantial opportunity cost.

2.2 CDS Basics

CDSs were invented in order to resolve the issues that accompany hedging against risk (as described in Section 2.1).

As shown in Figure 2.2, a CDS is an agreement between two **counterparties**, or opposing groups, in which the buyer (in this case, the portfolio manager) pays a fixed periodic coupon, also known as the **deal spread**, to the seller in exchange for protection against a credit event associated with the buyer's bond.

Figure 2: Cash flows in a single name CDS contract.

In our example, the portfolio manager is the **protection buyer**. Let's say that the **protection seller** is a hedge fund. The hedge fund sells protection to the portfolio manager for \$10 million of senior debt, an amount known as the **notional amount**. In return, she has to pay the hedge fund an annual coupon rate of over 1%, or 100 basis points, for a period of five years. These \$100,000 payments are made quarterly, so she would have to pay 0.25% every quarter until the maturity date.

In the case of default, the hedge fund would have to pay a compensation equal to the notional amount minus the company's **recovery rate**. The recovery rate is defined as the amount that the company is able to give back to its debt holders after default. When a company goes into bankruptcy and is forced to default on its debt, whatever remains in the company's assets is paid out according to the firm's capital structure. This transaction allows the portfolio manager to do away with the bonds' associated credit risk while still keeping the bonds within her possession. If Alcoa Inc. does not default, the hedge fund can receive a fee and walk away without any losses.

Our example above can be described as a single-name CDS contract, in which the transfer of credit risk takes place between two parties. The protection buyer of a CDS contract transfers the credit risk to the CDS protection seller by paying a series of coupons until the contract terminates. In other words, the protection buyer is **short credit** by selling the credit risk of an underlying bond to the protection seller. Note that there is no involvement of the Alcoa Inc. in the transaction; this exchange only takes place between the two counterparties.

2.3 More on CDS Cash Flows and terminology

Although the cash flows involved in a CDS seem pretty simple in figure 2.2, the underlying mechanics of a CDS are a bit more complex. To understand this, let us look at the actual CDS data of Alcoa Inc. from Bloomberg¹. Figure 2.3 below displays many different variables such as RED code, Reference Entity et al. on the CDS of Alcoa Inc. for June 02, 2014. These are standard terms of CDS contracts that were set by the **International Swaps and Derivatives Association (ISDA)**, the organization that regulates over-the-counter derivatives. Let us go into more detail about what these variables are the exactly the cash flow works and what variables our portfolio manager has to consider.

Figure 3: CDS figures from Bloomberg

Some of these variables seem rather straightforward. **Reference Entity** refers to the name of the company for which protection has been bought, which, in this case, is Alcoa Inc. **Maturity** refers to the **tenor** or length of the contract. Bloomberg provides the length of the contract or the equivalent

¹The two most commonly used sources for CDS related data are Bloomberg and Markit, which we will discuss extensively in a later section.

maturity date. **Debt type**, labelled as 'Senior', refers to the seniority of the debt. The **notional amount** is printed as '10' or \$10 million 'USD' (US Dollars). The 'MM' between the amount and the currency refers to the type of restructuring of the contract. 'MM' stands for 'Modified Modified' Restructuring.

The two terms in this figure that are essential to understanding the cash flow are **Trd Sprd** (Trade Spread) and **Coupon**, both given in basis points (bp). In section 2.2, we stated that the protection buyer pays the protection seller a fixed coupon for purchasing protection. Until 2009, the two counterparties would agree on the coupon level before the trade, and as the market moved, this tradable coupon would vary. In this type of a contract, the present value of the contract (the current worth of a future sum of money) would be zero.

In April 2009 in North America, and June 2009 in Europe, CDS contracts were standardized such that dealers would have to quote fixed coupons of 100bp or 500bp in North America, or 25bp, 100bp, 500bp or 1000bp in Europe. The **Coupon** printed in the figure above is the fixed coupon for Alcoa Inc., which is 100bp or 1% of the notional. However, the dealers may not feel that this is the fair premium for protection. The hedge fund selling protection to the portfolio manager may feel that the fair premium should be 160bp, and not 100bp. This fair premium rate is the **Trd Sprd** in the figure above, labelled as 160.

Naturally, if the hedge fund believes that the fair premium should be 160bp, it would like to be compensated for receiving just 100bp in advance. The portfolio manager would have to make what is known as an **Upfront Payment**, labelled as **Cash Amount** in Figure 2.3. With the information for Alcoa given in the figure, this amount is Therefore, the total payments made by the portfolio manager over the life of the contract would look like Figure 2.3.

Figure 4: CDS cash flows when there is no credit event.

Figure 5: CDS cash flows when there is a credit event.

3 CDS Terminology

Here is a glossary of CDS terminology necessary for determining the pricing and cash flows associated with CDSs²:

Reference Entity refers to the legal entity that is the subject of a CDS contract (Alcoa Inc., in our example).

RED is a Markit product that stands for Reference Entity Database. Each entity/seniority pair has a unique six-digit RED code that matches the first six digits of the nine-digit RED pair code. Each entity also has a “preferred reference obligation,” which is the default reference obligation for CDS trades. A user can input either the six-digit RED code or the nine-digit RED pair code. The input “014B98” is the six-digit RED code for “Alcoa Inc.”.

Trade Date indicates the trade date of the CDS contract, as shown in the argument of the CDS function. In our example, the trade date is June 02, 2014 in `cds1`.

Maturity refers to the fixed date on which a CDS contract terminates. However, colloquially speaking, it can also represent the length of time remaining until that date. This length is also called the **tenor** of a CDS contract. The most commonly traded CDSs have maturities of five years. The protection buyer continues to make payments to the protection seller until the maturity of the contract or the occurrence of a credit event. The maturity is five years in `cds1`.

²Some of the definitions come from *Credit Derivatives Glossary* (Markit, 2009), *Standard Corporate CDS Handbook* (Leeming et al., 2010), *Credit Derivatives* (Green and Witschen, 2012), and *The Pricing and Risk Management of Credit Default Swaps, with a Focus on the ISDA Model* (White, 2013).

Notional is the amount of the underlying asset on which the payments are based. It is \$10 million in `cds1`.

Coupon is quoted in basis points (bps). It specifies the payment amount from the protection buyer to the seller on an annual basis. Coupons are paid quarterly. This contract has a coupon of 100 bps.

Spread is quoted in basis points per year. If, instead of using a fixed coupon and exchanging upfront fees, the buyer and seller of protection were to agree on a variable coupon, then the spread would be the coupon size that they agree on. It is quoted as 50 bps in `cds1`.

Here the user enters the CDS contract with "Alcoa Inc." as the underlying entity and sets the spread at 50 bps and the coupon at 100 bps. However, the valuation of a CDS contract requires neither the Reference Entity or the RED Code. She does not have to know that information to use the **CDS** package. As shown below, as long as she inputs the same Trade Date, `parSpread`, and maturity information, the valuation of the contract will be the same.

```
> library(CDS)
> cds2 <- CDS(TDate = "2014-04-15",
+           tenor = "5Y",
+           coupon = 100,
+           parSpread = 50)
```

Besides `parSpread`, a market participant can choose to specify either `ptsUpfront` or `upfront` to construct a CDS class object.³ `ptsUpfront` or `upfront` refer to points upfront (in %), and upfront payment (in dollar amount) of a CDS contract, respectively. One of the three arguments has to be specified in order to construct the CDS class object.

4 The ISDA Standard Model

The International Swaps and Derivatives Association (ISDA) has created a set of standard terms for CDS contracts, the so-called "Standard Model." This allows market participants to calculate cash settlement from conventional spread quotations, convert between conventional spread and upfront payments, and build the spread curve of a CDS. The **CDS** package implements the Standard Model, allowing users to value credit default swaps and calculate various risk measures associated with these instruments.

In April 2009 in North America, ISDA introduced a series of mandatory modifications to the CDS contract known as the "Big Bang Protocol." Among these changes were the standardization rules on the first accrual dates, fixed coupon rates (100 bps or 500 bps), and the recovery rate (40%).

An ISDA standard CDS contract specifies the following:⁴

Trade Date refers to the date of the trade.

³See Section 4 for definitions on both terms.

⁴Refer to the *ISDA Standard CDS Converter Specification* for details.

Maturity is the length of the contract. The most commonly traded contracts have a maturity of 5 years.

Maturity Date falls on one of the four dates (Mar/Jun/Sep/Dec 20th) in a year. One can add the maturity of the contract to the trade date; the next available date among those four dates is the maturity date.

Backstop Date is the date from which protection is provided,

$$\text{Backstop Date} = T - 60 \text{ Calendar Days.}$$

Notional Amount is in millions.

Standard Coupon is either 100 or 500 bps per year for CDS contracts in North America.

Recovery Rate is the estimated percentage of par value that bondholders will receive after a credit event. It is commonly reported in percentage of notional value. CDS contracts for corporate bonds assume a 40% recovery rate for valuation purposes.

Par Spread is the spread value which makes the present value of a CDS contract zero. It is quoted in basis points.

Upfront Payment is quoted in the currency amount. Since a standard contract is traded with fixed coupons, upfront payment is introduced to reconcile the difference in contract value due to the difference between the fixed coupon and the par spread. There are two types of upfront, dirty and clean. Dirty upfront (**Cash Settlement Amount**) refers to the market value of a CDS contract. Clean upfront is dirty upfront less any accrued interest payment, and is also called the **Principal**.

Points Upfront , or simply **points**, are quoted as a percentage of the notional amount. They represent the upfront payment excluding the accrual payment. High yield CDS contracts are often quoted in points upfront. The protection buyer pays the upfront payment if points upfront are positive, and the buyer is paid by the seller if the points are negative.

The Standard Model allows market participants to convert between the par spread and the upfront payment, and compute the cash settlement amount for a standard contract. A few key assumptions and definitions used when valuing a Standard CDS contract are the following:⁵

Trade Date (T) means 11:59pm on the trade date.

Days of Protection is the number of days from Maturity Date to Trade Date.

Mark-to-market (MTM) represents the contract value to the protection buyer. It is computed by discounting the expected protection leg and premium leg cashflows to T.

Accrued Premium is the premium that has accrued from accrual begin date to T where both dates are inclusive.

⁵Please refer to <http://bit.ly/1kg5qPw> for more information on the ISDA standard CDS model assumptions.

The ISDA also standardizes the interest rates used by the Standard Model in valuing a CDS contract. There are two types of rates used in valuing a USD denominated CDS contract: cash rates and swap rates. Cash rates are of the following maturities: one, two, three, and six month(s), and one year. They are provided by the British Bankers' Association (BBA). Swap rates are of maturity 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 20, 25, and 30 years, and are provided by ICAP (Markit, 2013). The Standard Model follows the conventions below for interpolation of the entire USD yield curve:

- The day count convention (DCC) for money market instruments and floating legs of the swaps is **ACT/360**.
- DCC for floating legs of the swaps is **30/360**.
- Payment frequency for fixed legs of the swaps is 6 months.
- Payment frequency for floating legs of the swaps is 3 months.⁶
- A business day calendar of weekdays (Monday to Friday) is assumed. Saturdays and Sundays will be the only non-business days.
- If a date falls on a non-business day, the convention used for adjusting coupon payment dates is **M** (Modified Following).

5 CDS Indices

Holding a portfolio of a disproportionate number of Alcoa Inc. bonds is naturally a risky idea. In the real world, most successful portfolio managers prefer to distribute their risk by holding a portfolio with hundreds, if not thousands, of different positions. Instead of holding a 100 million USD of Alcoa Inc. bonds, let's say our portfolio manager decides to reduce her risk by holding bonds of 100 different Investment Grade companies. This is known as **diversification**. Although this strategy reduces her exposure to the credit risk of any particular company, she hasn't reduced her exposure to factors that might affect a wide variety of assets simultaneously, such as interest rate risk or political risk. Fortunately, in the modern financial world, she has the option of purchasing multi-name CDSs, or CDS indices, which contain a basket of CDSs.

Moreover, if our portfolio manager has a high-risk appetite and wants to earn a higher return for her investors, she may invest a portion of her portfolio in bonds that have a lower credit rating but provide a higher yield. She may consider investing in a tranche of CDS indices known as CDX.NA.HY.

6 Pricing Sources

We compared the results from our package with results from Bloomberg and Markit. Interestingly, the results from Markit and Bloomberg were not always identical.

⁶See <http://www.fincad.com/derivatives-resources/wiki/swap-pricing.aspx> for details on floating and fixed legs calculation.

Figure 6: CDS figures from Markit.com

Figure 7: CDS figures from Bloomberg

The interest rate results were identical, at least until the fourth decimal place.

7 Using the CDS package

In the **CDS** package, we call the function `CDS` to construct an object of a class `CDS`. Below we show an example of how to construct a CDS contract in the package.

```
> library(CDS)
> cds1 <- CDS(entityName = "Alcoa Inc.",
+             RED = "49EB20",
+             TDate = "2014-04-15",
+             tenor = "5Y",
+             notional = 1e7,
+             coupon = 100,
+             parSpread = 50)
```

Currently, a market participant can conduct CDS-related calculations by using the **CDSW Calculator** on a Bloomberg Terminal or the Markit CDS Calculator.⁷ The **CDS** package provides tools for valuing a single-name CDS contract. The default setting allows a user to value a USD-denominated CDS contract following the Standard Model as mentioned in Section 4. She can also specify her own set of parameters to customize the calculation. We have illustrated the construction of a CDS contract using the **CDS** package in previous sections. In this section, we will demonstrate the use of the **CDS** package in more detail and provide a series of examples.

Recall that in Section 'Using the CDS package', a CDS class object called `cds1` has been constructed. Its maturity is five years. Its spread is set at 50 bps and its coupon at 100 bps. The notional amount is \$10 million. A user can call `summary` on a `cds1` to view essential information on the contract.

```
> summary(cds1)
```

Contract Type:	SNAC	TDate:	2014-04-15
Entity Name:	Alcoa Inc.	RED:	49EB20
Currency:	USD	End Date:	2019-06-20
Spread:	50	Coupon:	100
Upfront:	-256,577	Spread DV01:	5,086
IR DV01:	66.14	Rec Risk (1 pct):	90.03

In the summary output, it shows that the type of the CDS contract is "SNAC". Trade Date refers to the trade date and is April 15, 2014. Reference Entity (called `entityName` in the package) refers to the entity name of the CDS contract and is "Alcoa Inc.". The RED code is "49EB20" as specified by the user. spread shows that the quoted spread for the contract is 50 bps and the coupon is 100 bps as shown in the coupon field. upfront indicates the dirty upfront payment in dollars or the cash settlement amount. It is -256,577 dollars, which means that from a buyer's perspective, the net present value of the remaining expected cashflows is -\$256,577.

To understand the remaining three items from the summary output (Spread DV01, IR DV01, and Rec Risk (1 pct)), one needs to understand **PV01**, an essential component to the mark-to-market

⁷The Markit CDS Calculator is available at <http://www.markit.com/markit.jsp?jspage=pv.jsp>.

calculation of a CDS contract. PV01 is the present value of a stream of 1 basis point payments at each CDS coupon date. It is sometimes referred to as the **CDS duration** or **risky duration**.

Analytically, PV01 can be calculated by

$$PV01 = \sum_t Df(t_i)S(t_i)B(t_i),$$

where

- i = coupon index,
- t_i = coupon date,
- $Df(t_i)$ = discount factor until t_i ,
- $S(t_i)$ = survival probability until t_i ,
- $B(t_i)$ = day count fraction at t_i .

We can thus calculate the principal amount (clean upfront payment) paid from the protection buyer to the seller using the following formula:

$$\text{Principal Amount} = (\text{Par Spread} - \text{Coupon}) \times PV01.$$

Using the concept of PV01, we show the calculation of the main risks (exposures) of a CDS position, **Spread DV01**. Spread DV01 reflects the risk duration of a CDS trade, also known as **Sprd DV01**, **Credit DV01**, **Spread Delta**, and just **DV01**.

It measures the sensitivity of a CDS contract mark-to-market to a parallel shift in the term structure of the par spread. DV01 should always be positive for a protection buyer since he or she is short credit, and a rising spread is a sign of credit deterioration. Starting with PV01 and taking the derivative with respect to the spread gives us:

$$\begin{aligned} PV\Delta &= \Delta(S - C) * PV01 \\ DV01\Delta &= \Delta \frac{\partial PV}{\partial S} \\ \Delta &= \Delta PV01 + (S - C) \frac{\partial PV01}{\partial S}, \end{aligned}$$

where S is the spread of the contract and C is the coupon.

Both DV01 and PV01 are measured in dollars and are equal if the spread equals the coupon. The Spread DV01 of cds1 is \$5,086.

IR DV01 is the change in value of a CDS contract for a 1 bp parallel increase in the interest rate curve. IR DV01 is, typically, a much smaller dollar value than Spread DV01 because moves in overall interest rates have a much smaller effect on the value of a CDS contract than does a move in the CDS spread itself. In cds1, the IR DV01 is \$66.14. **Recovery Risk 01** or Rec Risk (1 pct) as shown in the summary output, is the dollar value change in market value if the recovery rate used in the CDS valuation were increased by 1%. It is \$90.03 in cds1.

The default settings of valuing a CDS contract in the **CDS** package follow the Standard North American Corporate (SNAC) CDS Contract specifications.⁸ Below we list the ISDA specifications implemented in the **CDS** package. Additional default settings in the package which are not specified by the Standard Model, such as the default notional amount, are also listed.

- Currency: USD.
- Trade Date (T): the current business day.
- CDS Date: Mar/Jun/Sep/Dec 20th of a year.
- Maturity: five years.
- Maturity Date (End Date): It falls on a CDS date without adjustment.
- Coupon Rate: 100 bps.
- Notional Amount (MM): 10MM.
- Recovery Rate (%): 40% for senior debts.
- Premium Leg:
 - Payment Frequency: quarterly
 - DCC: ACT/360
 - Pay Accrued On Default: It determines whether accrued interest is paid on a default. If a company defaults between payment dates, there is a certain amount of accrued payment that is owed to the protection seller. “True” means that this accrued will need to be paid by the protection buyer, “False” otherwise. The default is “True,”
 - Adjusted CDS Dates: “F.” It means that it assumes the next available business day when a CDS date falls on a non-business day except the maturity date.
 - First Coupon Payment: It is the earliest Adjusted CDS Date after $T + 1$.
 - Accrual Begin Date (Start Date): It is the latest Adjusted CDS Date on or before $T + 1$.
 - Accrual Period: It is from previous accrual date (inclusive) to the next accrual date (exclusive), except for the last accrual period where the accrual end date (Maturity Date) is included.
- Protection Leg:
 - Protection Effective Date (Backdrop Date): $T - 60$ calendar days for credit events.
 - Protection Maturity Date: Maturity Date.
 - Protection Payoff: Par minus Recovery.

⁸See <http://www.cdsmodel.com/assets/cds-model/docs/Standard%20CDS%20Contract%20Specification.pdf> for details.

7.1 More on CDS pricing

CS10 is a method which calculates the change in value of the CDS contract when the spread of the contract increases by 10%. CS10 takes in a CDS class object formed by calling the CDS function. The CS10 of cds1 is \$25385.2.

```
> cds1.CS10 <- CS10(cds1)
> cds1.CS10
[1] 25385.2
```

A market participant can also update the CDS class objects she has constructed by calling the update method. It updates a CDS class object with a new spread and points upfront by specifying the relevant input.

```
> cds3 <- update(cds1, spread = 55)
```

cds3 is a new CDS class object with a spread of 55 bps; all other specifications of the contract are the same as those in cds1 since it is updated from cds1. One can also specify upfront (in dollar amount) or ptsUpfront (in bps) in the update method.

Besides calling the summary method, one can type in the name of the CDS class object in the current R Session and obtain a full description of the CDS contract.

```
> cds3

CDS Contract
Contract Type:          SNAC   Currency:          USD
Entity Name:           Alcoa Inc.  RED:          49EB20

```

There are three parts of the output. The first part "CDS Contract" provides basic information on the contract including "Contract Type", "Currency", "Reference Name" (called Entity Name in the package), "RED", "Trade Date", various dates related to the contract, and the day count conventions for cds3.

The second part of the output contains relevant risks measures of cds3. Price refers to the clean dollar price of the contract and is calculated by

$$\text{Price\&} = (1 - \text{Principal/Notional}) * 100$$

$$\& = 100 - \text{Points Upfront.}$$

The price of cds3 is 102.24, greater than 100. A CDS will have a price greater than 100 if the points upfront are negative; that is, the CDS buyer needs to receive money to obtain protection because he promises to pay a coupon of, say, 100 even if the spread is 60. This is analogous to a bond investor paying more than the face value of a bond because current interest rates are lower than the coupon rate on the bond.

"Default Prob" refers to the default probability which is the estimated probability of default for each maturity by a given time. It can be approximated by

$$\text{Default Prob} \approx \left[1 - \exp\left(\frac{rt}{1-R}\right) \right],$$

where r is the spread, t is the time to maturity, and R is the recovery rate. The default probability for cds3 is 4.7%.

"Default Expo" refers to the exposure to the default of a CDS contract based on the formula below.

$$\text{Default Exposure} = (1 - \text{Recovery Rate}) * \text{Notional} - \text{Principal.}$$

The last part of the output reports the interest rates used in the calculation.

Calling the function `getRates` also produces the rates used in building a curve for CDS valuation.

```
> cds3Rates <- getRates(date = "2014-04-15")
```

The output consists of two list objects. The first list contains rates of various maturities. They are directly obtained from the Markit website based on the specifications (Markit, 2013).

	expiry	matureDate	rate	type
1	1M	2014-05-19	0.001517	M
2	2M	2014-06-17	0.001923	M
3	3M	2014-07-17	0.002287	M

4	6M	2014-10-17	0.003227	M
5	1Y	2015-04-17	0.005465	M
6	2Y	2016-04-17	0.005105	S
7	3Y	2017-04-17	0.009265	S
8	4Y	2018-04-17	0.01347	S
9	5Y	2019-04-17	0.01715	S
10	6Y	2020-04-17	0.02016	S
11	7Y	2021-04-17	0.02263	S
12	8Y	2022-04-17	0.02458	S
13	9Y	2023-04-17	0.026265	S
14	10Y	2024-04-17	0.02759	S
15	12Y	2026-04-17	0.029715	S
16	15Y	2029-04-17	0.03182	S
17	20Y	2034-04-17	0.033635	S
18	25Y	2039-04-17	0.03442	S
19	30Y	2044-04-17	0.03478	S

The second list reports the specific day count conventions and payment frequencies regarding the interest rate curve used.

```

8 Conclusion

In this paper, we describe the basics of a CDS contract and the ISDA Standard Model. We also provide a simple collection of tools to implement the Standard Model in **R** with the CDS package. Moreover, the flexibility of **R** itself allows users to extend and modify this package to suit their own needs and/or create their preferred models for valuing CDS contracts. An **R** package, *backtest* Campbell et al. (2007), provides facilities to explore portfolio-based conjectures about credit default swaps. It is possible to use the *backtest* package based on the output from the CDS package. Before reaching that level of complexity, however, CDS provides a good starting point for valuing credit default swaps.
